## 1 Introduction

Haskell is a delightful language. Yet, for some reason, it doesn't seem to have its rightful place in terms of popularity in industry. Why is it so? Is it inherently hard to learn and therefore only the brave enough students and corporations dare to use it, or could it be that the syntax is perplexing to the amateur eye? It is my belief that with some syntax changes that give a greater familiarity to the new user, there would be no language more compelling than (the new) Haskell. In an attempt to achieve that familiarity, I present some new syntax, of which some is closer to the imperative/OOP style (to attract more already experienced programmers from these languages), some is closer to mathematics (in which most programmers should be experienced) and some is closer to natural language (in which we are all already experienced).

## 2 Language Description

An lcases program consists of a set of value, type and predicate definitions along with type theorems. The "main" value determines the program's behaviour. Constants and functions are all considered values and they have no real distinction other than the fact that functions have a function type and constants don't. Functions (just like "values") can be passed to other functions as arguments or can be returned as a result of other functions.

### Program example: extended euclidean algorithm

```
// type definitions

tuple_type Coeffs
value (previous, current) : Int x Int

tuple_type GcdAndCoeffs
value (gcd, a, b) : Int x Int x Int

// algorithm

init_a_coeffs, init_b_coeffs: all Coeffs
= (1, 0), (0, 1)

ext_euc: (Int, Int) => GcdAndCoeffs
= ext_euc_rec(init_a_coeffs, init_b_coeffs)

ext_euc_rec: (Coeffs, Coeffs, Int, Int) => GcdAndCoeffs
= (a_coeffs, b_coeffs, x, cases) =>
  0 => (x, a_coeffs.previous, b_coeffs.previous)
  y => ext_euc_rec(next <- a_coeffs, next <- b_coeffs, y, x -> mod <- y)
  where
    next: Coeffs => Coeffs
    = fields => (current, previous - x / y * current)

// reading, printing and main
```

```

read_two_ints : (Int x Int)WithIO
= print <- "Please give me 2 ints";
  get_line ;> split_words o> apply(from_string)to_all o> ints =>
  ints -> length -> cases =>
    2 => ints -> with_io
    ... => io_error <- "You didn't give me 2 ints"

print_gcd_equation : (Int, Int, GcdAndCoeffs) => (EmptyValue)WithIO
= (x, y, fields) => print("gcd = " + gcd + " = " + sum_string)
  where
    sum_string : String
      = a + " * " + x + " + " + b + " * " + y

main : (EmptyValue)WithIO
= read_two_ints ;> ints =>
  print_gcd_and_coeffs(ints.1st, ints.2nd, ext_euc(ints.1st, ints.2nd))

```

## 2.1 Basic Value Expressions

### 2.1.1 Literals and Identifiers

#### Literals

- *Examples*

```

1 2 17 42 -100
1.61 2.71 3.14 -1234.567
'a' 'b' 'c' 'x' 'y' 'z' '.' ',' '\n'
"Hello World!" "What's up, doc?" "Alrighty then!"

```

- *Description*

We have literals for the four basic types: Int, Real, Char, String. These are the usual integers, real numbers, characters and strings. The exact specification of literals is the same as in the Haskell report.

QUESTION integers are different?

- *Grammar*

$\langle literal \rangle ::= \langle literal \rangle$

TODO add the grammar from the haskell report

#### Identifiers

- *Examples*

```

x y z
a1 a2 a3
funny_identifier
unnecessarily_long_identifier
apply()to_all

```

- *Description*

An identifier is a string used as the name of a value. It is first used in the definition of the value (see

”value definition” section 2.4) and later used in the definition of other values that use that defined value. An identifier starts with a lower case letter and is followed by lower case letters or underscores. It also possible to have a pairs of parentheses in the middle of an identifier (see ”parenthesis function application” section 2.1.3). Finally, an identifier can be ended with a digit.

- *Grammar*

$\langle identifier \rangle ::= [a-z]( [a-z\_ ] | '()' [a-z\_ ] )^* [ [0-9] ]$

## 2.1.2 Parenthesis, Tuples and Lists

### Parenthesis

- *Examples*

```
(1 + 2)
in
(1 + 2) * 3

(x => f(x) + 1) and (s => "f(val) + 1 is: " + s)
in
val -> (x => f(x) + 1) -> to_string -> (s => "f(val) + 1 is: " + s)

("Line is: " + line) and (get_line ;> line => print("Line is: " + line))
in
do(3)times <- (get_line ;> line => print("Line is: " + line))
```

- *Description*

An expression is put in parenthesis to prioritize it or isolate it in a bigger expression. The expressions that can be placed in parenthesis are "simple" operator or function expressions (or a mix). In this context, "simple" means that the "cases" syntax does not appear anywhere in the expression (see "cases" syntax section 2.3.3).

- *Grammar*

```
 $\langle \text{paren-expr} \rangle ::= '(\langle \text{simple-expr} \rangle)'$ 
 $\langle \text{simple-expr} \rangle ::= \langle \text{simple-op-expr} \rangle \mid \langle \text{simple-func-expr} \rangle$ 
 $\langle \text{simple-op-expr} \rangle ::= (\langle \text{op-arg} \rangle \text{ '⋈' } \langle \text{op} \rangle \text{ '⋈' }) + (\langle \text{op-arg} \rangle \mid \langle \text{simple-func-expr} \rangle)$ 
```

### Tuples

- *Examples*

```
(1, "What's up, doc?")
(2, "Alrighty then!", 3.14)
(x, y, z, w)
(1, my_function, (x, y, z) => (x ^ 2 + y ^ 2 + z ^ 2) ^ (1/2))
```

- *Description*

Tuples are used to group many values (of possibly different types) into one. The type of the tuple can be either the product of the types of the subvalues or a defined tuple\_type which is equivalent to the aforementioned product type i.e. the product type is in the definition of the tuple\_type (see "tuple\_type" section 2.5.2). For example, the type of the second example above could be:

```
Int x String x Real
```

or:

```
MyType
```

assuming "MyType" has been defined in a similar way to the following:

```
tuple_type MyType
value (my_int, my_string, my_real) : Int x String x Real
```

- *Grammar*

$\langle tuple \rangle ::= '(\langle basic-or-simple-expr \rangle (', \sqcup' \langle basic-or-simple-expr \rangle )+ ' )'$

$\langle basic-or-simple-expr \rangle ::= \langle basic-expr \rangle \mid \langle simple-expr \rangle$

$\langle basic-expr \rangle ::= \langle literal \rangle \mid \langle identifier \rangle \mid \langle tuple \rangle \mid \langle list \rangle \mid \langle paren-func-app \rangle$

## Lists

- *Examples*

```
[1, 2, 17, 42, -100]
[1.61, 2.71, 3.14, -1234.567]
["Hello World!", "What's up, doc?", "Alrighty then!"]
[x => x + 1, x => x + 2, x => x + 3]
[x, y, z, w]
```

- *Description*

Lists are used to group many values of the same type into one. The type of the list is `ListOf(A)s` where `A` is the type of every value inside. Therefore, the types of the first four examples are:

```
ListOf(Int)s
ListOf(Real)s
ListOf(String)s
(A)And(Int)AddTo(B) --> ListOf(A => B)s
```

And the last list is only legal if `x`, `y`, `z` and `w` all have the same type. Assuming they do and it's the type `T`, the type of the list is:

```
ListOf(T)s
```

- *Grammar*

$\langle list \rangle ::= '[ \langle basic-or-simple-expr \rangle (', \sqcup' \langle basic-or-simple-expr \rangle )^* ]'$

### 2.1.3 Parenthesis Function Application

#### Examples

```
f(x)
f(x, y, z)
(x)to_string
apply(f)to_all
apply(f)to_all(1)
```

### Description

Function application in lcases can be done in many different ways in an attempt to maximize readability. In this section, we discuss the ways function application can be done with parenthesis. In the first two examples, we have the usual mathematical function application which is also used in most programming languages and should be familiar to the reader. That is, function application is done with the arguments of the function in parenthesis seperated by commas and **appended** to the function identifier.

We extend this idea by allowing the arguments to be **prepended** to the function identifier (third example). Finally, it is also possible to have the arguments **inside** the function identifier provided the function has been **defined with parentheses inside the identifier**. For example, below is the definition of "apply()to\_all":

```

apply()to_all: (A => B, ListOf(A)s) => ListOf(B)s
  = (f, cases) =>
    empty => empty
    non_empty:l => non_empty:(f <- l.head, apply(f)to_all <- l.tail)

```

The actual definition doesn't matter at this point, what matters is that the identifier is "apply(to\_all" with the parentheses **included**. This is very useful for defining functions where the argument in the middle makes the function application look and sound more like natural language.

In is possible that many parentheses pairs are present in a single function application (last example). The arguments are always inserted to the function from **left to right**. Therefore, when multiple parentheses pairs are present the arguments of the leftmost parentheses are inserted first then the next ones to the right and so on.

## Grammar

$$\begin{aligned} \langle \textit{paren-func-app} \rangle &::= \\ &\quad \langle \textit{arguments} \rangle \mid ( \langle \textit{identifier-with-arguments} \rangle \mid \langle \textit{identifier} \rangle ) \\ &\quad \mid ( \langle \textit{identifier-with-arguments} \rangle \mid \langle \textit{identifier} \rangle ) \langle \textit{arguments} \rangle \\ &\quad \mid \langle \textit{identifier-with-arguments} \rangle \\ \langle \textit{arguments} \rangle &::= \text{ ' ( ' } \langle \textit{basic-or-simple-expr} \rangle \text{ ( ' , } \sqcup \text{ ' } \langle \textit{basic-or-simple-expr} \rangle \text{ ) }^* \text{ ' ) ' } \\ \langle \textit{identifier-with-arguments} \rangle &::= \\ &\quad [\text{a-z}] \langle \textit{id-char-or-paren-id-char} \rangle^* ( \langle \textit{arguments} \rangle [\text{a-z\_}] \langle \textit{id-char-or-paren-id-char} \rangle^* ) + [ [0-9] ] \\ \langle \textit{id-char-or-paren-id-char} \rangle &::= [\text{a-z\_}] \mid \text{ ' ( ' } [\text{a-z\_}] \end{aligned}$$

## 2.2 Operators

### 2.2.1 Function Application Operators

Operator	Type
$\rightarrow$	$(A, A \Rightarrow B) \Rightarrow B$
$\leftarrow$	$(A \Rightarrow B, A) \Rightarrow B$

The function application operators “->” and “<-” are a different way to apply functions to arguments than the usual parenthesis function application. They are meant to look like arrows that point from the argument to the function. These operators are very useful for chaining many function applications without the clutter of having to open and close parentheses for each one of the functions. For example, assuming we have the following functions with the behaviour suggested by their names and types:

```

apply()to_all : (A => B, ListOf(A)s) => ListOf(B)s
string_length: String => Int
filter_with : (A => Bool, ListOf(A)s) => ListOf(A)s
is_odd : Int => Bool
sum_ints : ListOf(Int)s => Int

```

And a list of strings:

```
strings : ListOf(String)s
```

Here is a simple way to get the number of characters in all the strings that have odd length:

```

chars_in_odd_length_strings : Int
= strings -> apply(string_length)to_all -> filter_with(is_odd) -> sum_ints

```

Ofcourse this can be done equivalently using the other operator:

```

chars_in_odd_length_strings : Int
= sum_ints <- filter_with(is_odd) <- apply(string_length)to_all <- strings

```

These operators can also be used together to put a function between two arguments if that function is commonly used that way in math (or if it looks better for a certain function). For example the "mod" function can be used like so:

```
x -> mod <- y
```

Instead of:

```
mod(x, y)
```

## 2.2.2 Function Composition Operators

Operator	Type
<code>o&gt;</code>	$(A \Rightarrow B, B \Rightarrow C) \Rightarrow (A \Rightarrow C)$
<code>&lt;o</code>	$(B \Rightarrow C, A \Rightarrow B) \Rightarrow (A \Rightarrow C)$

The function composition operators "`o>`" and "`<o`" are used to compose functions, each one in the corresponding direction. The use of the letter 'o' is meant to be similar to the mathematical function composition symbol 'o' and the symbols '>', '<' are used so that the operator points from the function which is applied first to the function which is applied second. A neat example using function composition is the following. Assuming we have the following functions with the behaviour suggested by their names and types:

```

split_words : String => ListOf(String)s
apply()to_all : (A => B, ListOf(A)s) => ListOf(B)s
reverse_string: String => String
merge_words : ListOf(String)s => String

```

We can reverse the all the words in a string like so:

```

reverse_words : String => String
= split_words o> apply(reverse_string)to_all o> merge_words

```

Ofcourse this can be done equivalently using the other operator:

```

reverse_words : String => String
= merge_words <o apply(reverse_string)to_all <o split_words

```

### 2.2.3 Arithmetic Operators

Operator	Type
$\wedge$	(A)ToThe(B)Gives(C) $\rightarrow$ (A, B) $\Rightarrow$ C
*	(A)And(B)MultiplyTo(C) $\rightarrow$ (A, B) $\Rightarrow$ C
/	(A)Divides(B)To(C) $\rightarrow$ (B, A) $\Rightarrow$ C
+	(A)And(B)AddTo(C) $\rightarrow$ (A, B) $\Rightarrow$ C
-	(A)SubtractsFrom(B)To(C) $\rightarrow$ (B, A) $\Rightarrow$ C

The usual arithmetic operators work as they are expected, similarly to mathematics and other programming languages for the usual types. However, they are generalized. The examples below show their generality:

```
>> 1 + 1
2
>> 1 + 3.14
4.14
>> 'a' + 'b'
"ab"
>> 'w' + "ord"
"word"
>> "Hello " + "World!"
"Hello World!"
>> 5 * 'a'
"aaaaa"
>> 5 * "hi"
"hihihihihi"
>> "1,2,3" - ',', '
"123"
```

Let's analyze further the example of addition. The type can be read as such: the '+' operator has the type (A, B)  $\Rightarrow$  C, provided that the type statement (A)And(B)AddTo(C) holds. This statement being true, means that addition has been defined for these three types (see section "type logic" 2.6 for more on type statements). For example, by the examples above we can deduce that the following propositions are true (in the order of the examples):

```
(Int)And(Int)AddTo(Int)
(Int)And(Real)AddTo(Real)
(Char)And(Char)AddTo(String)
(Char)And(String)AddTo(String)
(Int)And(Char)MultiplyTo(String)
(Int)And(String)MultiplyTo(String)
(Char)SubtractsFrom(String)To(String)
```

This allows us to use the familiar arithmetic operators in types that are not necessarily numbers but it is somewhat intuitively obvious what they should do in those other types. Furthermore, their behaviour can be defined by the user for new user defined types!

### 2.2.4 Comparison and Boolean Operators

Operator	Type
<code>= /=</code>	$(A) \text{HasEquality} \rightarrow (A, A) \Rightarrow \text{Bool}$
<code>&gt; &lt; &gt;= &lt;=</code>	$(A) \text{HasOrder} \rightarrow (A, A) \Rightarrow \text{Bool}$
<code>&amp;  </code>	$(\text{Bool}, \text{Bool}) \Rightarrow \text{Bool}$

The comparison and boolean operators behave the same as in Haskell and very similarly to most programming languages. The main difference is that in `lcases` the "equals", "and" and "or" operators have the symbol once (`= & |`) rather than twice (`== && ||`).

### 2.2.5 Environment Operators

Operator	Type
<code>; &gt;</code>	$(E) \text{IsAnEnvironment} \rightarrow (E(A), A \Rightarrow E(B)) \Rightarrow E(B)$
<code>;</code>	$(E) \text{IsAnEnvironment} \rightarrow (E(A), E(B)) \Rightarrow E(B)$

#### Example program

```
main : (EmptyValue)WithIO
  = print_string <- "Hello! What's your name?" ; get_line ;> name =>
    print_string("Oh hi " + name + "! What's your age?") ; get_line ;> age =>
    print_string( "Oh that's crazy " + name + "! I didn't expect you to be " + age + "!");
```

The example above demonstrates the use of the environment operators in the `WithIO` environment, which is how `IO` is done in `lcases`. Some light can be shed on how this is done, if we take a look at the types (as always!):

```
print_string : String => (EmptyValue)WithIO
get_line : (String)WithIO

print_string <- "Hello! ... " : (EmptyValue)WithIO
print_string("Oh hi...") : (EmptyValue)WithIO
print_string("Oh that's crazy...") : (EmptyValue)WithIO

; : (E)IsAnEnvironment --> (E(A), E(B)) => E(B)
print_string("Oh hi...") ; get_line : (String)WithIO
  where
    (WithIO)IsAnEnvironment, E = WithIO, A = EmptyValue, B = String

age => print_string("Oh that's crazy...") : String => (EmptyValue)WithIO

;> : (E)IsAnEnvironment --> (E(A), A => E(B)) => E(B)
print_string("Oh hi...") ; get_line ;> age => print_string("Oh that's crazy...") : (EmptyValue)WithIO
  where
    (WithIO)IsAnEnvironment, E = WithIO, A = String, B = EmptyValue

print_string <- "Hello..." ; get_line : (String)WithIO
name => print_string("Oh hi ... (till the end) : String => (EmptyValue)WithIO

print_string <- "Hello..." ; get_line ;> name =>
print_string("Oh hi ... (till the end)
  : (EmptyValue)WithIO
```

Therefore, `"main : (EmptyValue)WithIO"` checks out. The key here is to remember that function expressions extend to the end of the whole expression. Therefore, we have `"name => ... (till the end)"` and `"age => ... (till the end)"` as the second arguments of the two occurrences of the `";>"` operator.

## Description

The environment operators are used to combine values that have some environment. Environments are also represented by types. These types take other types as arguments and produce new types (just like `ListOf()`s). The values of the type `E(A)` where `(E)IsAnEnvironment` have inside both a value of type `A` together with all the values that the environment `E` has. The `WithIO` environment specifically, not only has other values inside it (concerning IO stuff), but also does IO effects.

The effect of the operator `";"` described in words is the following: given a value of type `E(A)` (which is a value of type `A` in an environment of type `E`) and a value of type `E(B)` (which is a value of type `B` in an environment of type `E`), combine those two values and produce the value of type `B` which was inside the second value in a new environment of type `E` that is produced by combining the two environments. The overall effect produces a value of type `B` in an environment of type `E` and therefore the overall value is of type `E(B)`.

Note that the value of type `A` inside the first value is not used anywhere. This is mostly used when `A = EmptyValue`. This happens because values of type `E(EmptyValue)` are used for their environment only (e.g. `print_string(...)` : `(EmptyValue)WithIO`).

How the two environments of the `E(A)` and `E(B)` values are combined to produce the new environment is specific to the environment type `E`. When the environments are `WithIO` environments specifically, the effect is that the new environment does the IO of the first environment first, then does the IO of the second environment only if the IO of the first environment does not produce an IO error.

The effect of the operator `";>"` described in words is the following: given a value of type `E(A)` (which is a value of type `A` in an environment of type `E`) and a value of type `A => E(B)` (which is a function from a value of type `A` to a value of type `B` in an environment of type `E`), combine those two values by passing the value of type `A` inside the first value as an argument to the second value. This results in a value of type `E(B)` (which is a value of type `B` in an environment of type `E`). Then, produce this value of type `B` in a new environment of type `E` that is produced by combining the first environment with the resulting environment. The overall effect produces a value of type `B` in an environment of type `E` and therefore the overall value is of type `E(B)`.

### 2.2.6 Operator Expressions

#### Examples

```
1 + 2
1 + x * 3 ^ y
"Hello " + "World!"
x -> f -> g
f o> g o> h
x = y
x >= y - z & x < 2 * y
get_line ; get_line ;> line => print("Second line: " + line)
```

#### Description

Operator expressions are expressions that use operators. Operators act like two-argument-functions that are placed in between their arguments. Therefore, they have function types and they act as it is described in their respective sections above this one.

An operator expression might have multiple operators. The order of operations is explained in the next section: "Complete Table, Precedence and Associativity".

Just like functions, the sub-expressions that act as arguments to an operator, must have types that match the types expected by the operator.

It is possible to end an operator expression with a function. This is mostly useful with the ">" operator (see previous section: "Environment Operators"), but it is also possible with the following operators: ">", ">", "<".

## Grammar

$\langle op\text{-}expr \rangle ::= ( \langle op\text{-}arg \rangle \langle op \rangle \langle op \rangle ) + ( \langle op\text{-}arg \rangle \mid \langle simple\text{-}func\text{-}expr \rangle \mid \langle cases\text{-}func\text{-}expr \rangle )$

$\langle op\text{-}arg \rangle ::= \langle basic\text{-}expr \rangle \mid \langle paren\text{-}expr \rangle$

$\langle op \rangle ::= \text{'>'} \mid \text{'<-'} \mid \text{'>'} \mid \text{'<'} \mid \text{'^'} \mid \text{'*'} \mid \text{'/'} \mid \text{'+'} \mid \text{'-'} \mid \text{'='} \mid \text{'/='} \mid \text{'>'} \mid \text{'<'} \mid \text{'>='} \mid \text{'<='} \mid \text{'\&'} \mid \text{'|'} \mid \text{'>'} \mid \text{';'}$

### 2.2.7 Complete Table, Precedence and Associativity

Below we have the complete table of lcases operators along with their types and their short descriptions.

Operator	Type	Description
->	$(A, A \Rightarrow B) \Rightarrow B$	Right function application
<-	$(A \Rightarrow B, A) \Rightarrow B$	Left function application
o>	$(A \Rightarrow B, B \Rightarrow C) \Rightarrow (A \Rightarrow C)$	Right function composition
<o	$(B \Rightarrow C, A \Rightarrow B) \Rightarrow (A \Rightarrow C)$	Left function composition
^	$(A)\text{ToThe}(B)\text{Gives}(C) \text{ --> } (A, B) \Rightarrow C$	General exponentiation
*	$(A)\text{And}(B)\text{MultiplyTo}(C) \text{ --> } (A, B) \Rightarrow C$	General multiplication
/	$(A)\text{Divides}(B)\text{To}(C) \text{ --> } (B, A) \Rightarrow C$	General division
+	$(A)\text{And}(B)\text{AddTo}(C) \text{ --> } (A, B) \Rightarrow C$	General addition
-	$(A)\text{SubtractsFrom}(B)\text{To}(C) \text{ --> } (B, A) \Rightarrow C$	General subtraction
= /=	$(A)\text{HasEquality} \text{ --> } (A, A) \Rightarrow \text{Bool}$	Equality operators
> < >= <=	$(A)\text{HasOrder} \text{ --> } (A, A) \Rightarrow \text{Bool}$	Order operators
&	$(\text{Bool}, \text{Bool}) \Rightarrow \text{Bool}$	Boolean operators
; >	$(E)\text{IsAnEnvironment} \text{ --> } (E(A), A \Rightarrow E(B)) \Rightarrow E(B)$	Monad bind
;	$(E)\text{IsAnEnvironment} \text{ --> } (E(A), E(B)) \Rightarrow E(B)$	Monad then

Below we have the table of precedence and associativity of the lcases operators.

Operator	Precedence	Associativity
->	10	Left
<-	9	Right
o> <o	8	Left
^	7	Right
* /	6	Left
+ -	5	Left
= /= > < >= <=	4	None
&	3	Left
	2	Left
; > ;	1	Left

## 2.3 Function Expressions

Function expressions are either simple function expressions or function expressions that use the "cases" syntax. For more details and examples of both see the following sections.

### Grammar

$\langle func\text{-}expr \rangle ::= \langle simple\text{-}func\text{-}expr \rangle \mid \langle cases\text{-}func\text{-}expr \rangle$

#### 2.3.1 Simple Function Expressions

##### Examples

`a => 17 * a + 42`

`(x, y, z) => (x ^ 2 + y ^ 2 + z ^ 2) ^ (1 / 2)`

##### Description

Simple function expressions are used to define functions or be part of bigger expressions as anonymous functions. They are comprised by their parameters and their body. A parameter is either an identifier or the keyword "fields" (see next section: "fields" Special Parameter). The parameters are either only one, in which case there is no parenthesis, or they are many, in which case they are in parenthesis, separated by commas. The parameters and the body are separated by an arrow ("`=>`"). The body is a "simple" operator expression meaning that there is no "cases" syntax inside the operator expression.

### Grammar

$\langle simple\text{-}func\text{-}expr \rangle ::= \langle parameters \rangle \text{ '=>' } \langle simple\text{-}op\text{-}expr \rangle$

$\langle parameters \rangle ::= \langle parameter \rangle \mid \text{'(' } \langle parameter \rangle \text{ ( ' , ' } \langle parameter \rangle \text{ ) + '}'$

$\langle parameter \rangle ::= \langle identifier \rangle \mid \text{'fields'}$

### 2.3.2 "fields" Special Parameter

### 2.3.3 "cases" Syntax

#### Examples

```
print_sentimental_bool : Bool => (EmptyValue)WithIO = cases =>
  true => print <- "It's true!! :)"
  false => print <- "It's false... :("

or_type TrafficLight
values green | amber | red

print_sentimental_traffic_light : Bool => (EmptyValue)WithIO
= cases =>
  green => print <- "It's green! Let's go!!! :)"
  amber => print <- "Go go go, fast!"
  red => print <- "Stop right now! You're going to kill us!!"

is_not_red : TrafficLight => Bool
= cases =>
  green => true
  amber => true
  red => false

is_seventeen_or_forty_two : Int => Bool
= cases =>
  17 => true
  42 => true
  ... => false

traffic_lights_match : (TrafficLight, TrafficLight) => Bool
= (cases, cases) =>
  green, green => true
  amber, amber => true
  red, red => true
  ... => false

gcd : (Int, Int) => Int
= (x, cases) =>
  0 => x
  y => gcd(y, x -> mod <- y)

is_empty : ListOf(A)s => Bool
= cases =>
  empty => true
  non_empty:anything => false

apply()to_all: (A => B, ListOf(A)s) => ListOf(B)s
= (f, cases) =>
  empty => empty
  non_empty:list => non_empty:(f <- list.head, apply(f)to_all <- list.tail)
```

## Description

"cases" is a keyword that works as a special parameter. The difference is that instead of giving the name "cases" to that parameter, it let's you pattern match on the possible values of that parameter and return a different result for each particular case (hence the name!).

The "cases" keyword can only be used on parameters that have either one of the basic types (Int, Real, Char, String) or an `or_type` (e.g. Bool, ListOf(A)s).

The last case can be "... => (body of default case)" to capture all remaining cases while dismissing the value (e.g. `is_seventeen_or_forty_two` example), or it can be "some\_identifier => (body of default case)" to capture all remaining cases while being able to use the value with the name "some\_identifier" (e.g. "y" in `gcd` example).

It is possible to use the "cases" keyword in multiple parameters to match on all of them. By doing that, each case represents a particular combination of values for the parameters involved (e.g. `traffic_lights_match` example).

A function expression that uses the "cases" syntax must contain the "cases" keyword in at least one parameter. The number of matching expressions in all cases must be the same as the number of parameters with the "cases" keyword.

## Grammar

$\langle \text{cases-func-expr} \rangle ::= \langle \text{cases-parameters} \rangle \text{'\_=>\_'} \langle \text{cases} \rangle$

$\langle \text{cases-parameters} \rangle ::= \langle \text{cases-parameter} \rangle \mid \text{'('} \langle \text{cases-parameter} \rangle \text{' , ' } \langle \text{cases-parameter} \rangle \text{' ) + '}'$

$\langle \text{cases-parameter} \rangle ::= \langle \text{parameter} \rangle \mid \text{'cases'}$

$\langle \text{cases} \rangle ::= \langle \text{case} \rangle + [ \langle \text{default-case} \rangle ]$

$\langle \text{case} \rangle ::= \text{'\n'} \langle \text{indentation} \rangle \langle \text{matching} \rangle \text{' ( ' , ' } \langle \text{matching} \rangle \text{' ) * ' \_=>\_ ' } \langle \text{simple-op-expr} \rangle$

$\langle \text{default-case} \rangle ::= \text{'\n'} \langle \text{indentation} \rangle \text{' ... \_=>\_ ' } \langle \text{simple-op-expr} \rangle$

$\langle \text{matching} \rangle ::= \langle \text{literal} \rangle \mid \langle \text{identifier} \rangle [ \text{' : ' } \langle \text{identifier} \rangle ]$

## 2.4 Value Definitions

### 2.4.1 Basic Structure

#### Examples

```
foo : Int
    = 42
```

```
val1, val2, val3 : Int, Bool, Char
    = 42, true, 'a'
```

```
int1, int2, int3 : all Int
    = 1, 2, 3
```

```

succ : Int => Int
      = +1

f : (Int, Int, Int) => Int
  = (a, b, c) => a + b * c

```

## Description

To define a new value you give it a name, a type and an expression. It is possible to group value definitions by separating the names, the types and the expressions with commas. It is also possible to use the keyword "all" to give the same type to all the values.

## Grammar

$\langle \text{value-definitions} \rangle ::= \langle \text{identifiers} \rangle \text{'\_:'\_'} ( \langle \text{types} \rangle \mid \text{'all'} \langle \text{type} \rangle ) \text{'\n\_='} \langle \text{value-expressions} \rangle$

$\langle \text{identifiers} \rangle ::= \langle \text{identifier} \rangle ( \text{'\_','} \langle \text{identifier} \rangle )^*$

$\langle \text{types} \rangle ::= \langle \text{type} \rangle ( \text{'\_','} \langle \text{type} \rangle )^*$

$\langle \text{value-expressions} \rangle ::= \langle \text{value-expression} \rangle ( \text{'\_','} \langle \text{value-expression} \rangle )^*$

### 2.4.2 "where" Expressions

#### Examples

```

sort : (A)HasOrder --> ListOf(A)s => ListOf(A)s
      = cases =>
          empty => empty
          non_empty:l => sort(less_l) + l.head + sort(greater_l)
          where
            less_l : ListOf(A)s
              = filter_with(x => x < l.head, l.tail)
            greater_l : ListOf(A)s
              = filter_with(x => x >= l.head, l.tail)

tuple_type Coeffs
value (previous, current) : Int x Int

tuple_type GcdAndCoeffs
value (gcd, a, b) : Int x Int x Int

ext_euc: (Int, Int) => GcdAndCoeffs
      = ext_euc_rec((1, 0), (0, 1))

ext_euc_rec: (Coeffs, Coeffs, Int, Int) => GcdAndCoeffs
      = (a_coeffs, b_coeffs, x, cases) =>
          0 => (x, a_coeffs.previous, b_coeffs.previous)
          y => ext_euc_rec(next <- a_coeffs, next <- b_coeffs, y, x -> mod <- y)
          where
            next: Coeffs => Coeffs
              = fields => (current, previous - x / y * current)

```

**Description** "where" expressions are used

## Grammar

### 2.4.3 "main" Value

## 2.5 Types

### 2.5.1 Type expressions

#### Examples

Int

String => String

Int x Int

Int x Int => Real

A => A

(A => B, B => C) => (A => C)

((A, A) => A, A, ListOf(A)s) => A

((B, A) => B, B, ListOf(A)s) => B

(T)HasStringRepresentation --> T => String

#### Description

Examples	Description
Int Char String	Base types
A => A (A => B, B => C) => (A => C)	Polymorphic types. A, B, C ... are type variables

#### Differences from Haskell

lcases	haskell	difference description
A => A	a => a	Type variables for polymorphic types are

## Grammar

$\langle type \rangle ::= \langle type-application \rangle \mid \langle product-type \rangle \mid \langle function-type \rangle$

$\langle type-application \rangle ::= [ \langle types-in-paren \rangle ] \langle type-identifier \rangle ( \langle types-in-paren \rangle ( [A-Za-z] )^* )^* [ \langle types-in-paren \rangle ]$

$\langle \text{types-in-paren} \rangle ::= '(\langle \text{type} \rangle (', ' \langle \text{type} \rangle)^* ')$   
 $\langle \text{type-identifier} \rangle ::= [A-Z] ([A-Za-z])^*$   
 $\langle \text{product-type} \rangle ::= \langle \text{product-subtype} \rangle ( ' \times ' \langle \text{product-subtype} \rangle )^+$   
 $\langle \text{product-subtype} \rangle ::= '(\langle \text{function-type} \rangle | \langle \text{product-type} \rangle )^* | \langle \text{type-application} \rangle$   
 $\langle \text{function-type} \rangle ::= \langle \text{input-types-expression} \rangle ' \Rightarrow ' \langle \text{one-type} \rangle$   
 $\langle \text{input-types-expression} \rangle ::= \langle \text{one-type} \rangle | \langle \text{two-or-more-types-in-paren} \rangle$   
 $\langle \text{one-type} \rangle ::= \langle \text{type-application} \rangle | \langle \text{product-type} \rangle | '(\langle \text{function-type} \rangle )^*$   
 $\langle \text{two-or-more-types-in-paren} \rangle ::= '(\langle \text{type} \rangle (', ' \langle \text{type} \rangle )^+ ')$

## 2.5.2 Tuple Types

### Definition Examples

```

tuple_type Name
value (first_name, last_name) : String x String

tuple_type ClientInfo
value (name, age, nationality) : Name x Int x String

tuple_type Date
value (day, month, year) : Int x Int x Int

tuple_type (A)And(B)
value (a_value, b_value) : A x B

tuple_type (ExprT)WithPosition
value (expr, line, column) : ExprT x Int x Int

```

### Usage Examples

```

giorgos_info : ClientInfo
= (("Giorgos", "Papadopoulos"), 42, "Greek")

john_info : ClientInfo
= (("John", "Doe"), 42, "American")

name_to_string : Name => String
= fields => "First Name: " + first_name + "\nLast Name: " + last_name

print_name_and_nationality : ClientInfo => (EmptyValue)WithIO
= fields => print(name -> name_to_string + "\nNationality: " + nationality)

print_error_in_expr : (SomeDefinedExprT)WithPosition => (EmptyValue)WithIO
= ewp =>
  print(
    "Error in the expression:" + es +

```

```

    "\nAt the position: (" + ls + ", " + cs + ")"
  )
  where
    es, ls, cs : all String
    = ewp.expr->to_string, ewp.line->to_string, ewp.column->to_string

```

## Description

Tuple types group many values into a single value. They are specified by their name, the names of their sub-values and the types of their subvalues. They generate projection functions for all of their subvalues by using a '.' before the name of the subvalue. For example the ClientInfo type above generates the following functions:

```

.name : ClientInfo => String
.age : ClientInfo => Int
.nationality : ClientInfo => String

```

These functions shall be named "postfix functions" as they can just be appended to their argument.

## Definition Grammar

```

<tuple-type-definition> ::=
  'tuple_type' <type-application> '\nvalue' '(' <identifier> (',' <identifier>)* ')' ' : ' <product-type>

```

### 2.5.3 Or Types

#### Examples

```

or_type Bool
values true | false

```

```

or_type Possibly(A)
values the_value:A | no_value

```

```

or_type ListOf(A)s
values non_empty:HeadAndTailOf(A)s | empty

```

```

tuple_type HeadAndTailOf(A)s
value (head, tail) : A x ListOf(A)s

```

```

is_empty : ListOf(A)s => Bool
  = cases =>
    empty => true
    non_empty:anything => false

get_head : ListOf(A)s => Possibly(A)
  = cases =>
    empty => no_value
    non_empty:list => the_value:list.head

```

## Description

Values of an or\_type are one of many cases that possibly have other values inside. The cases which have other values inside are followed by a semicolon and the type of the internal value. The same syntax can be used for matching that particular case in a function using the "cases" syntax, with the difference that after the colon, we write the name given to the value inside. Or\_types and basic types are the only types on which the "cases" syntax can be

used. The cases of an `or_type` which have a value inside create functions. For example, the case `"non_empty"` of a list creates the function `"non_empty:"` for which we can say:

```
non_empty: : HeadAndTailOf(A)s => ListOf(A)s
```

Similarly:

```
the_value: : A => Possibly(A)
```

These functions shall be named "prefix functions" as they are prepended to their argument. For example:

```
head_and_tail : HeadAndTailOf(Int)s
  = (1, [2, 3, 4])
```

```
list : ListOf(Int)s
  = non_empty:head_and_tail
```

These functions can be used like any other function as arguments to other functions. For example:

```
heads_and_tails_to_lists : ListOf(HeadAndTailOf(A)s)s => ListOf(ListOf(A)s)s
  = apply(non_empty:)to_each
```

## Definition Grammar

Addition/Subtraction:

```
+ : (A)HasAddition => (A, A) => A
- : (A)HasSubtraction => (A, A) => A
```

Equality and ordering:

```
= : (A)HasEquality => (A, A) => Bool
<= : (A)HasOrder => (A, A) => Bool
>= : (A)HasOrder => (A, A) => Bool

(fmap)<inside> — (W)IsAWrapper --> (A => B, W(A)) => W(B) — Apply inside operator
(<*>)<wrapped_inside> — (W)IsAWrapper --> (W(A => B), W(A)) => W(B) — Order operators

better as postfix functions
```

### Examples in Haskell

```
data ClientInfo =
  ClientInfoC String Int String
```

```
data WithPosition a =
  WithPositionC a Int Int
```

```
data Pair a b =
  PairC a b
```

### Examples in Haskell

```
{-# language LambdaCase #-}
```

```
data Bool =
  Ctrue | Cfalse
```

```
data Possibly a =
  Cwrapper a | Cnothing
```

```
data ListOf_s a =
  Cnon_empty (CNonEmptyValueListOf_s a) | Cempty
```

```
data NonEmptyValueListOf_s a =
  CNonEmptyValueListOf_s a (ListOf_s a)
```

```
is_empty :: ListOf_s a => Bool
is_empty = \case
  Cempty => Ctrue
  Cnon_empty (CNonEmptyValueListOf_s head tail) => Cfalse
```

```
get_head :: ListOf_s a => Possibly a
get_head = \case
  Cempty => Cnothing
  Cnon_empty (CNonEmptyValueListOf_s head tail) => Cwrapper head
```

### Examples in Haskell

```
foo :: Int
foo = 42
```

```

val1 :: Int
val1 = 42
val2 :: Bool
val2 = true
val3 :: Char
val3 = 'a'

```

```

int1 :: Int
int1 = 1
int2 :: Int
int2 = 2
int3 :: Int
int3 = 3

```

```

succ :: Int => Int
succ = \x => x + 1

```

```

f :: Int => Int => Int => Int
f = \a b c => a + b * c

```

Or Types the following have automatically generated functions:
